

6.1800 Spring 2024

Lecture #13: The application layer

serving content as content evolves

bandwidth-based scheduling:

can we allocate specific amounts of bandwidth to some traffic?

round robin: can't handle variable packet sizes
(and in its most basic form doesn't allow us to weight traffic differently)

deficit round robin: handles variable packet sizes
(even within the same queue), near-perfect fairness and low packet processing overhead

deficit round robin also doesn't require a mean packet size, which is another good thing

the quantums for each queue are chosen to be **proportionate to the packet sizes**. too big and we have poor short-term fairness, too small and it just takes too long to build credit.

in each round:

for each queue q:

if q is not empty:

q.credit += q.quantum

while q.credit >= size of next packet p:

q.credit -= size of p

send p

else:

q.credit = 0

You won't be able to find these new emoji on your keyboard just yet, though. While version 15.1.0 of the Unicode was approved on Sept. 12 ([you can read all of it here](#)), there's always a lag between the approval and its release. [Emojipedia](#) had estimated that the new emoji would be available in early 2024.

Phoenix, lime and brown mushroom are only a few of the many new emojis coming in iOS 17.4.

Emojipedia

standardizations let us communicate across machines

TCP, DNS, OSPF (link-state routing), etc., all have standards that describe the protocols in detail including packet formats

CAIDA's IPv4 AS Core,
January 2020
(<https://www.caida.org/projects/cartography/as-core/2020/>)

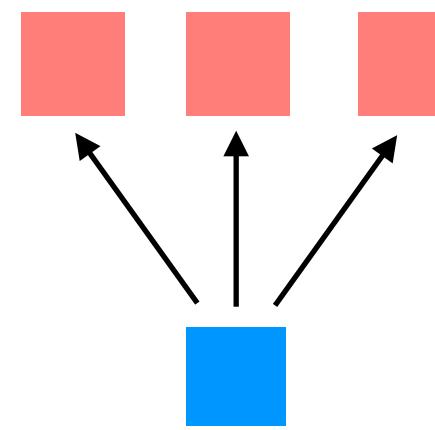

today: how do all of the lower layers affect application-layer
protocols? specifically, how do we **deliver content** on the
Internet?

how do we share a file — or **deliver content** — on the Internet?

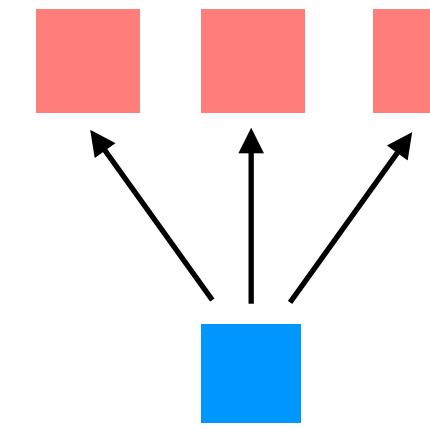

how do we share a file — or **deliver content** — on the Internet?

client-server

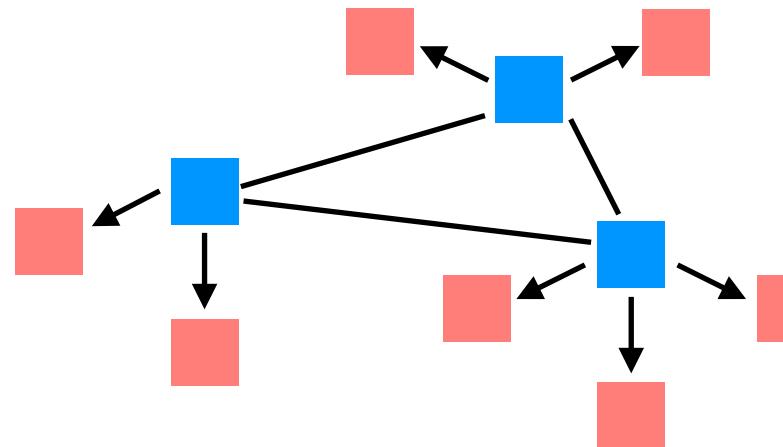

how do we share a file — or **deliver content** — on the Internet?

client-server

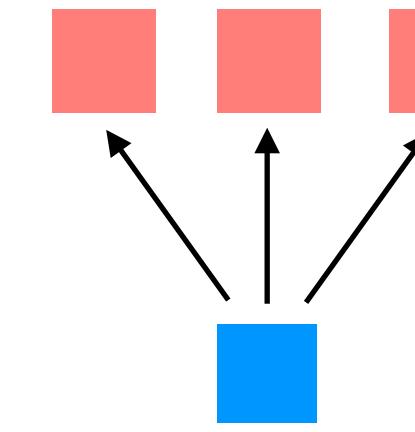

CDNs

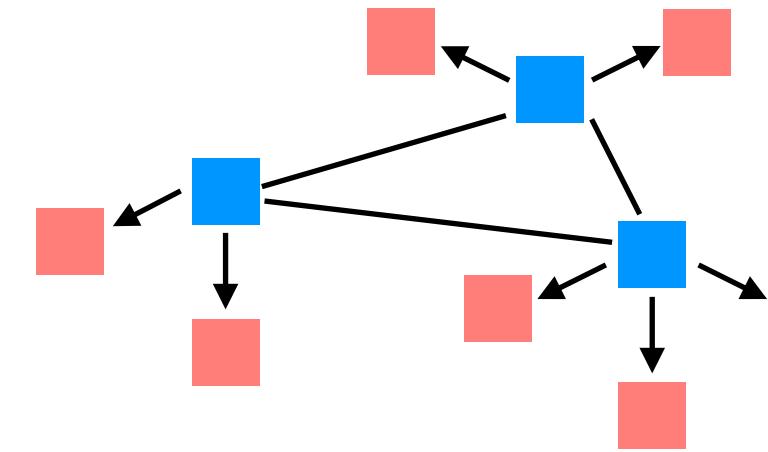

how do we share a file — or **deliver content** — on the Internet?

P2P

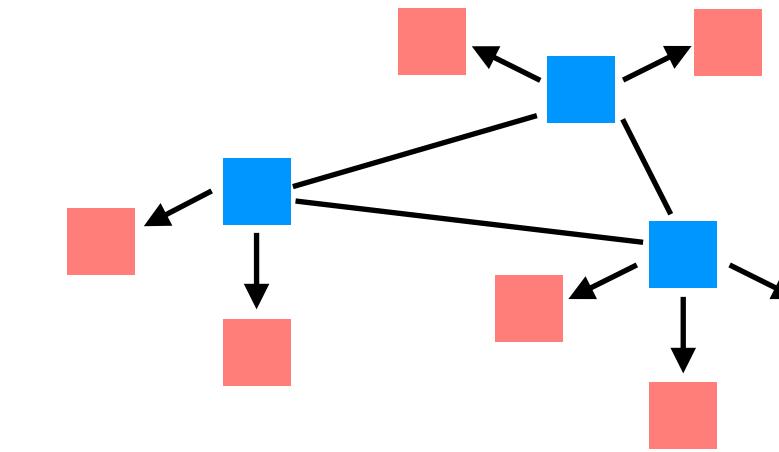

how do we share a file — or **deliver content** — on the Internet?

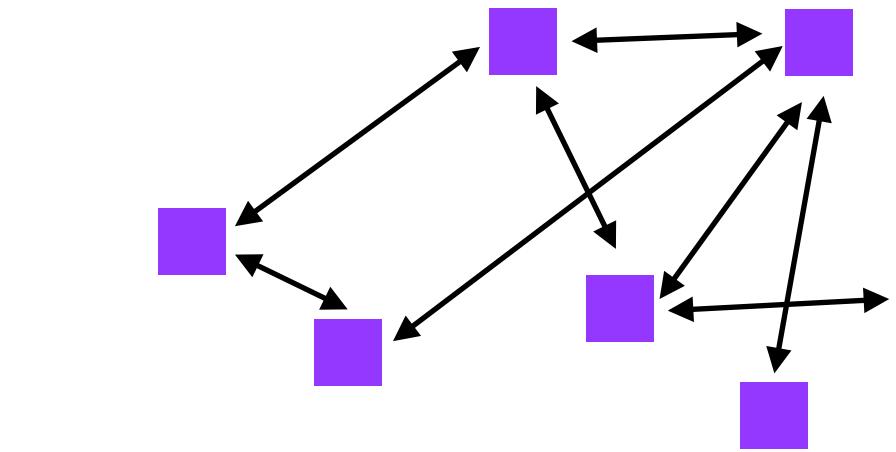

client-server

CDNs

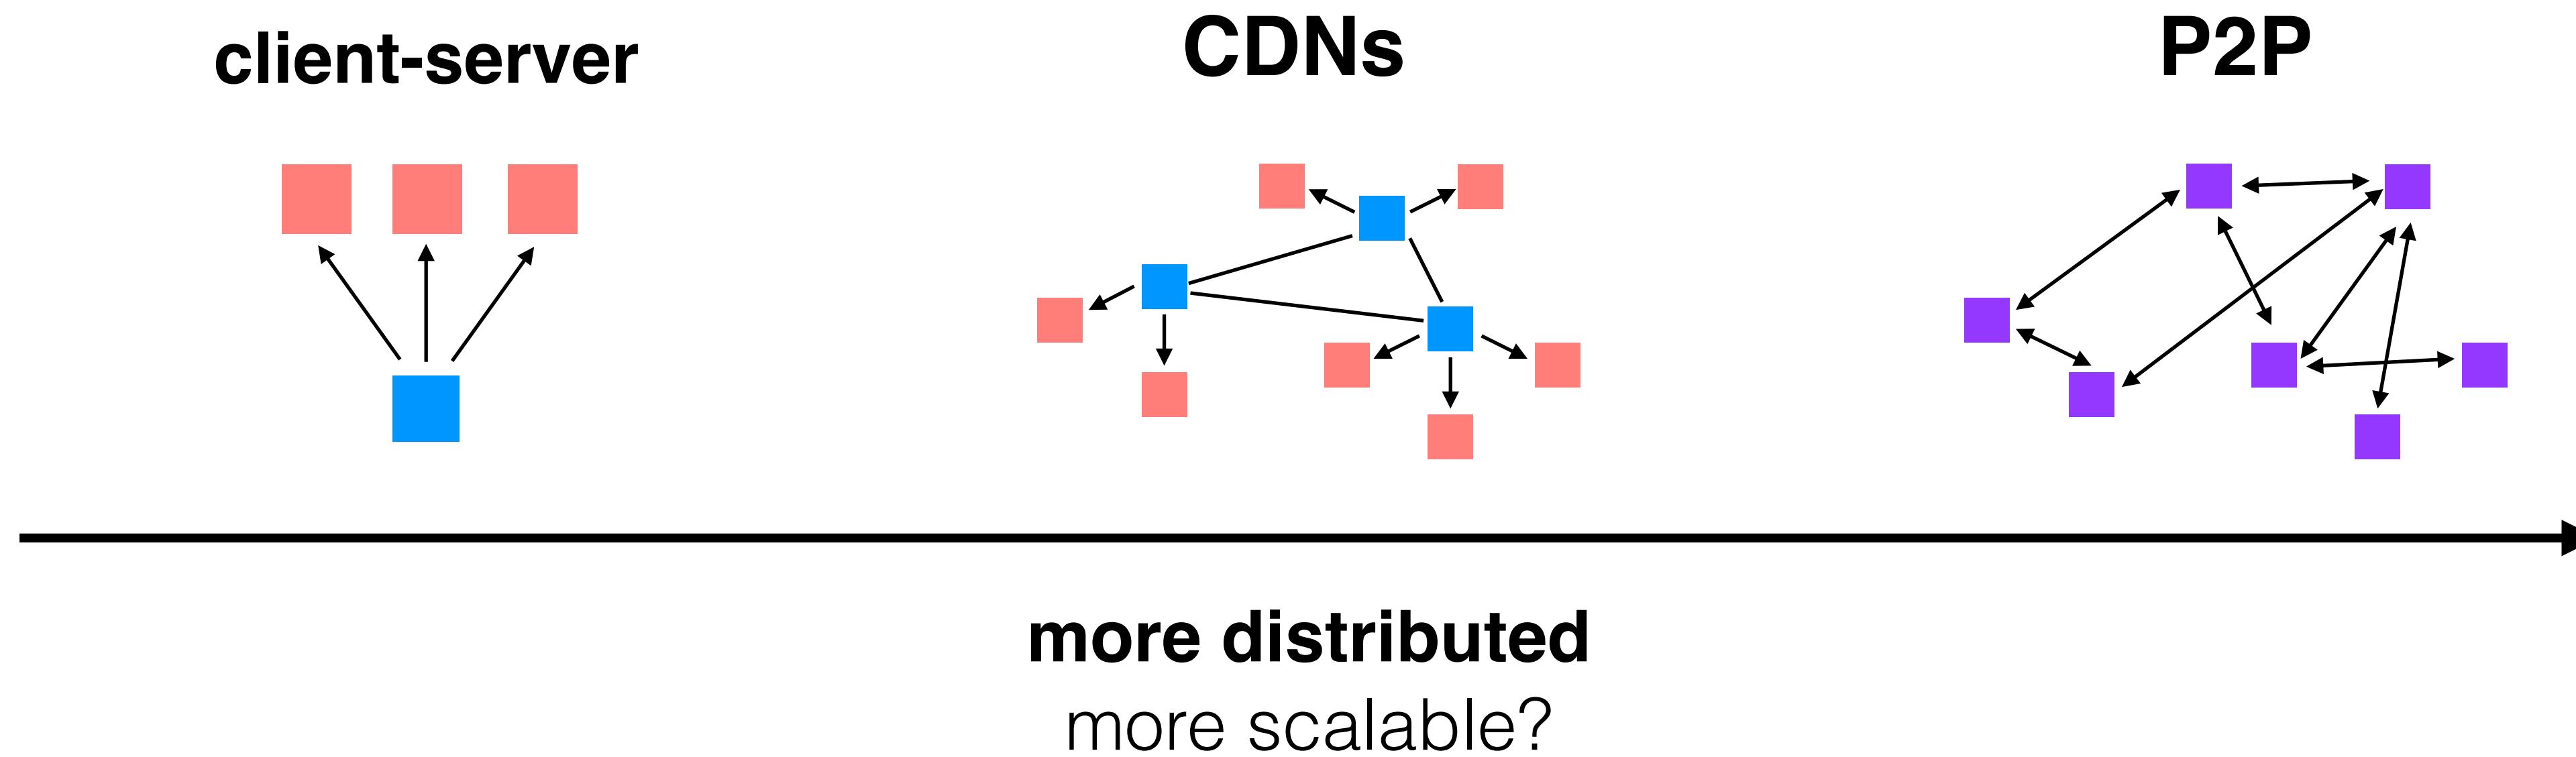

P2P

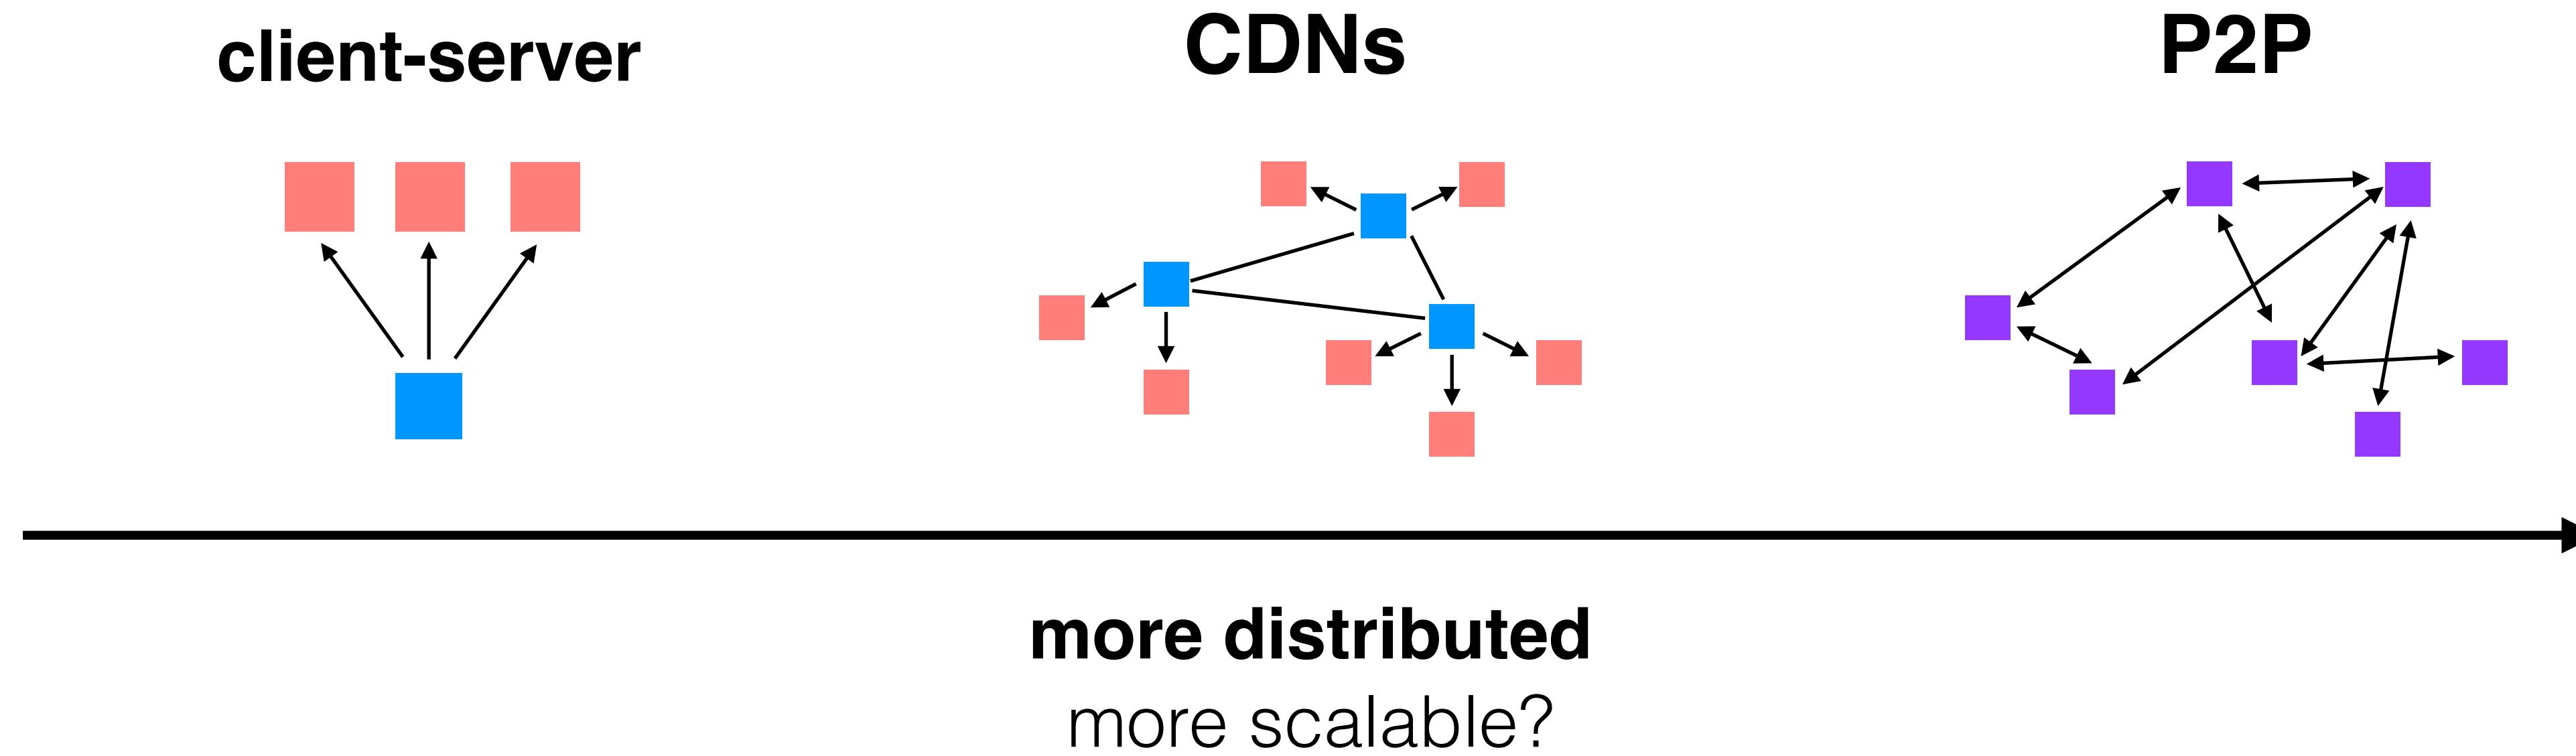

more distributed
more scalable?

how do we share a file — or **deliver content** — on the Internet?

we know that **a client-server model is (relatively) simple, but doesn't scale well**; let's understand more about the other two technologies, to see where they end up in terms of complexity, scalability, etc.

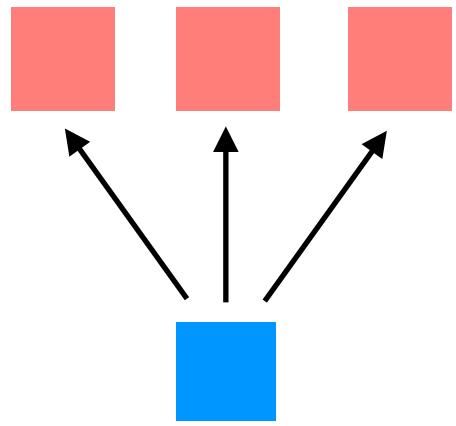

how do we share a file — or **deliver content** — on the Internet?

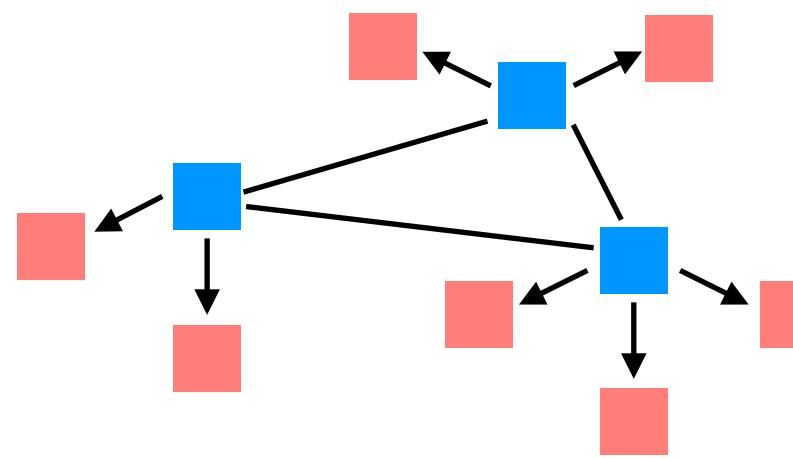

we know that **a client-server model is (relatively) simple, but doesn't scale well**; let's understand more about the other two technologies, to see where they end up in terms of complexity, scalability, etc.

as part of this endeavor, we'll also see why the underlying network matters in these designs

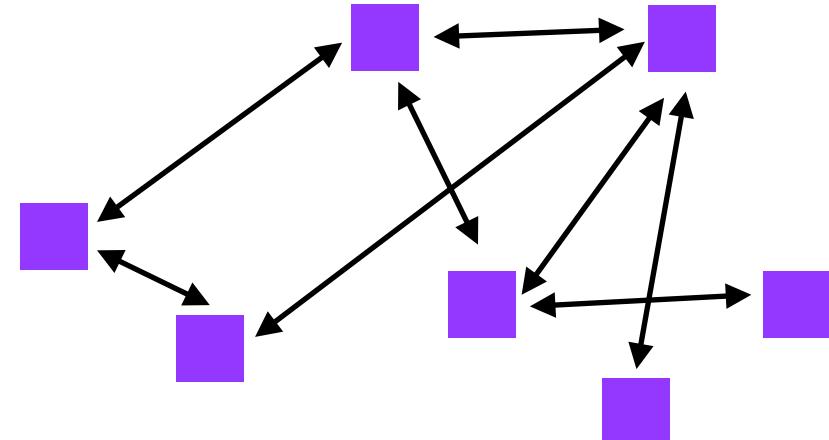

client-server

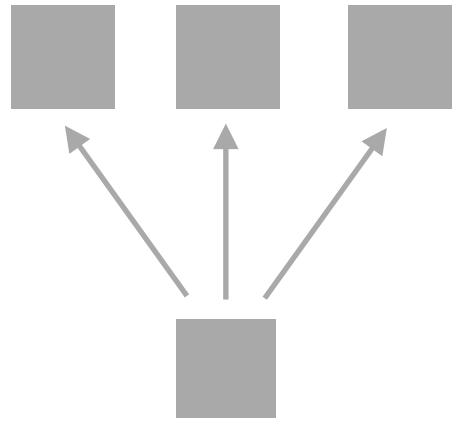

CDNs

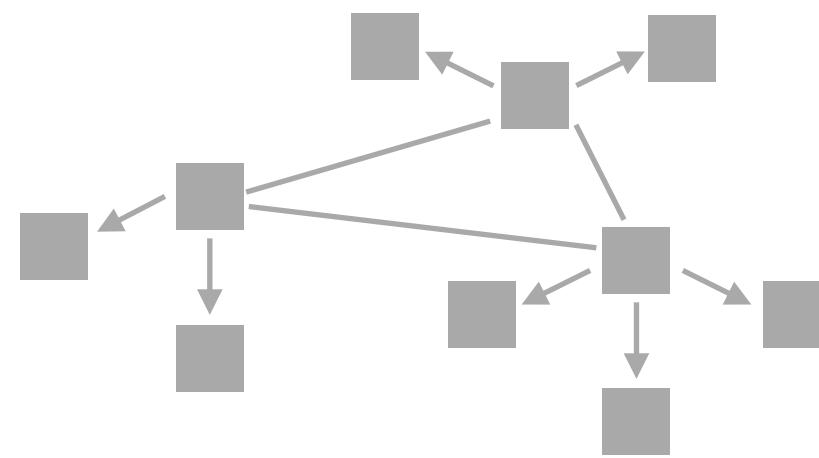

P2P

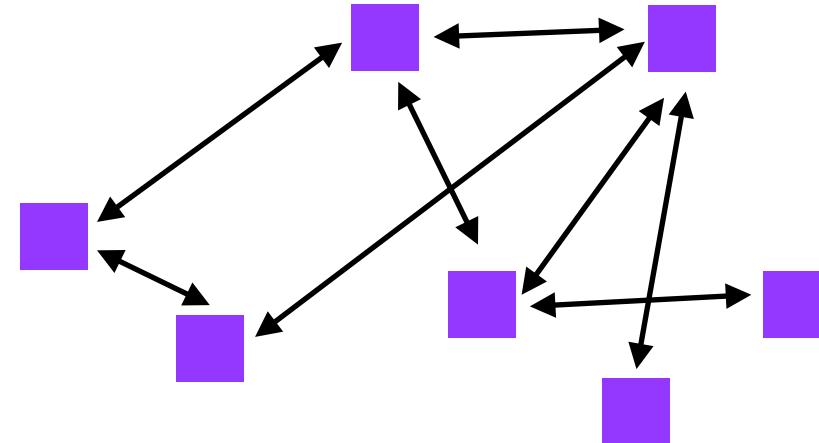

client-server

the technologies for sharing content on the Internet have changed as the way we use the Internet has changed

CDNs

P2P

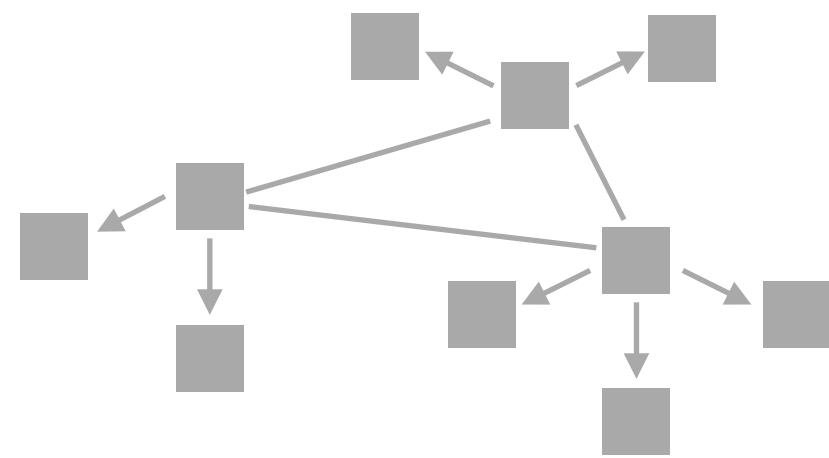

client-server

the technologies for sharing content on the Internet have changed as the way we use the Internet has changed

CDNs

the underlying network affects how well these technologies work, and there are also interesting challenges in terms of how to keep data up-to-date and **consistent** across multiple machines, and how to deal with **failures**

these are challenges we'll address starting after spring break
